

Computational Semantics and Natural Language Understanding 2025-2026

Project Assignment

Writing Recommendations

As published in the general guidelines, the final report should be 6 page long (11pt font). It should be research-oriented, and you can make it look like a published article. You can download the latex/word format files for [here](#) (or any other conference).

It is possible to use an appendix (that would be after the references) in order to add fine details/analysis that are not key to the project.

The data and code should be submitted each as a zip file. The information in data and code documentation, in the paper, and in the appendix should make the work as reproducible as possible.

Below are some recommendations on how to structure your report (but feel free to restructure it and use different titles on order to suit your project's needs).

1. Introduction: the goals of the introduction usually are:
 - to state the problem/research question
 - to explain why it is important/interesting
 - In case it is relevant, to explain the limitations of previous approaches to solve the problem/answer the question
 - to present your approach
 - to present the benefits of the approach and the main steps/experiments

It is recommended to include a figure/diagram/example in the introduction in order to make the subject of the project and the contributions clearer.

2. Related Work: It is not a mandatory section but it is often useful to include it in a separate section (beyond what is mentioned in the introduction or the other sections). It often fits well after the Introduction. Its goals are to give the necessary context and to stress the particularity of your work compared to previous research. It can be useful to structure it according to the different aspects that are relevant to the proposed approach (and not as "a list of papers").
3. Methods: It should include the presentation of your solution (it could take multiple sections). It is useful to explain the expectations you have from the proposed approach.
4. Experimental Evaluation: It is useful to map each experiment to a research question/sub-question, or explain in which way each experiment contributes to

the answer to the research question or to the validation of your proposed solution. It usually includes:

- Experimental Setting description
 - Key experimental results
 - Analysis (particularly important). It can include for example additional evaluations, ablation experiments, examples, error analysis, and/or discussions about the methods, results, insights, or limitations.
5. Conclusion: It summarizes the results and the key lessons.
 6. References: The references should use a uniform format. When using latex, I recommend using the [ACL anthology bib file](#) for papers published in main NLP conferences and journals. If the paper is published both as a conference/journal paper and as an ArXiv paper, please cite the conference/journal version. Please include the link to the paper in the citation and double check that the reference details are accurate.

Notes about Tables and Figures:

- It is useful to make the tables and figures clear so that they can represent well the content of the paper and be understandable without reading the paper. In particular, the captions along with the table/figure should be self-explanatory.
- When presenting the numbers, you can check for example whether it is needed to present *all* the numbers and whether to present absolute numbers vs. relative improvements. Also, usually statistical significance (in particular when the differences are small) can strengthen your arguments. See [this paper](#) for choosing the adequate significance test given the metric.
